1 Introduction

Qt-DAB is a program for decoding terrestrial DAB transmissions. The program is implemented in C++, with extensive use of Qt for its graphical appearance. Furthermore, it uses a number of existing open source libraries.

Qt-DAB is designed to run on both Windows and Linux (x64) computers as well as on RPI 2 and up. For *Windows* an *installer* is available, this installer will install the executable together with the required libraries. For *Linux (x64)* a so-called *appImage* is available, a kind of container, an executable file that contains next to the executable program the libraries needed to run.

For RPI's, however, one has to create an executable, no preconfigured, precompiled executable is available. This document contains a pretty detailed description on how to build such an executable.

The sourcetree for Qt-DAB contains a subdirectory *dab-mini* with sources, with configuration files and with a description on how to create an executable version with a minimal interface. This *dabMini* version is described in section 7.

Since no major changes to the Qt-DAB sources are expected, it was considered time to do some user documentation.

The structure of this guide is simple, in section 2 the GUI and GUI widgets are discussed, in section 3 command line parameters and the settings in the ini file, are discussed, in section 4 the configuration issues and options are discussed and the process of configuring and building is described.

In section 5 a brief overview is given on the DAB decoding process and the role of the various parts of the software. In section 6 the device interface as used in Qt-DAB is discussed and an explanation is given how to add a device to the configuration. Finally in section 7, a brief description is given of *dabMini*, a decoder version built on the same set of sources but with a minimal interface.

2 The GUI and GUI elements

When playing around with DAB I am usually interested in various properties of the signal, and I want to be in control. The GUI of Qt-DAB reflects that, there is an abundant amount of buttons, selectors and displays.

To keep things manageable, the GUI is built up as a central widget, a widget that is shown always, together with a number of other widgets that might - or might not - be made visible, depending on user's settings.

While the figure on the first page shows the GUI with all widgets, figure 1 shows the central widget, the one with (most of) the controls.

This main widget of the GUI (figure 1) can be thought to consist of three elements:

- the left part, handling control for channel and service;
- the top right part displaying information;

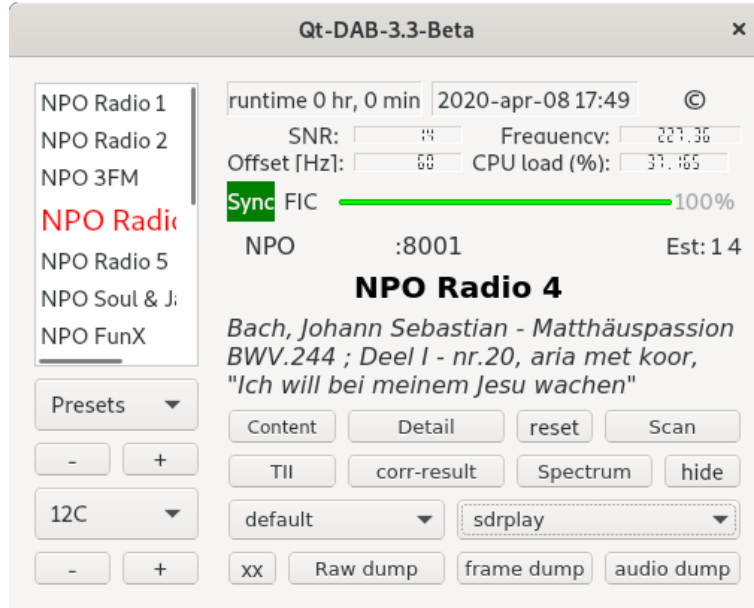

Figure 1: Qt-DAB: the main widget of the GUI

- the bottom right part, the various controls.

2.1 Control for channel and service

Central in the left part of the GUI is the list of services, these are the services detected in the currently selected channel. *Selecting* a service is by moving the cursor to the name of a service, and clicking with the *left* mouse button.

Below the list of services there is (from top to bottom)

- the combobox for the *presets*. A preset can be added to this list by clicking with the *right* mouse button on the name of the selected service in the service list¹. *Removing* an element from the list is by putting the cursor on the name of the service in the list of presets, and pressing the *shift* and *delete* button on the keyboard simultaneously.
- a *previous* (–) and a *next* (+) service button. With these button one can easily scan through the list of services.
- the combobox for *channel selection*. While DAB transmissions are in Band III, configuration provides options to select channels in the *L Band* or channels in a user defined band.

¹Clicking with the right mouse button on the name of a service that is not the selected one, will make a small widget visible with some information on the service pointed to

Figure 2: Qt-DAB, channel and service selection

- a *previous* (−) and a *next* (+) channel button, making it easy to scan through the channels in the selected band.

Note that the software will "remember" which channel was selected, and which service was selected. On program start up, these values will be taken as start value.

2.2 Displaying information

Figure 3: Qt-DAB, system wide information

Some general information is displayed in the top half of the right side of the GUI, see figure 3. The top line gives three elements

- the *run time*, the amount of time the program is running;
- the *current* time. Note that this time is taken from the time encoding in the transmission. When playing a recording, the time of the recording is shown rather than the current time of listening;
- the copyright symbol. Touching this with the cursor will reveal (a.o) the time and date the executable was built.

Below this line, there are boxes with labels:

- SNR, the measured signal/noise ratio. SNR is computed by comparing the signal strength in the null period of the DAB frame vs the average strength during transmission of the datablocks in the DAB frame;
- Frequency, the frequency, in MHz, of the selected channel;
- Offset, the frequency correction to be applied to the signal;
- CPU load, the overall CPU load, i.e. not only for running the program.

Below these - system related - pieces, there is a line with

- the *sync* flag, if *green*, time synchronization is OK;
- a *progressbar*, indicating the quality of decoding of the data in the FIC (Fast Information Channel). Since the FIC is "easier" to decode than most of the other data, a value less than 100 percent here usually indicates a poor reception.

The remainder here is devoted to describing the content of the reception, the name of the ensemble is displayed together with its ID. The name of the selected service is shown and below that name, the additional text, i.e. the *dynamic label* is shown.

The small number preceded by "Est:" gives - if shown - an indication of the transmitter being received. Since DAB is transmitted using a Single Frequency Network, one might receive data from more than one transmitter. Each transmitter encodes a unique identification in the transmitted signal, the transmitter identification information (two numbers, one for the network, one for the specific transmitter).

2.3 Control elements

The controls are grouped in the lower right half of the GUI, see figure 4. The control contains 12 push buttons and 2 comboboxes, they will be briefly discussed in the order from left to right, top to bottom.

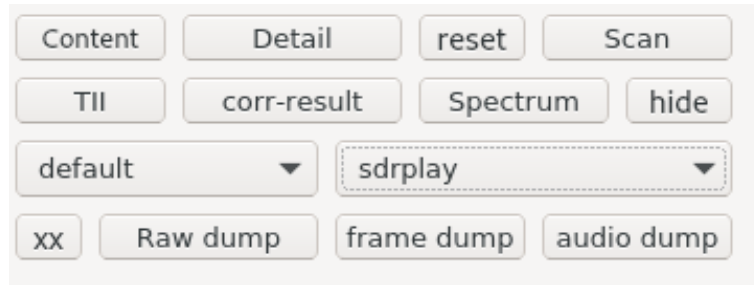

Figure 4: Qt-DAB: control elements

Content button Touching the button labeled *Content* will instruct the software to write a description of the content of the current ensemble to a file. First, a menu will appear with which the file can be selected. The file is written in ASCII and is readable by e.g. LibreOffice Calc or similar programs.

Detail button Touching the button labeled *Detail* will instruct the software to display detailed data on the selected service on a separate widget. Touching the button again will hide the widget.

Figure 5: Service details

The widget - figure 5 - shows the name and the identification of the service, it shows where the data of the service is located in the input stream, it shows the *protection* of

the data against errors, whether it is a DAB+ or a DAB transmission, and - if available - it shows the type of the service.

For DAB+ services three progress bars are shown, in case all three are 100 percent, decoding is 100 percent. If less, then there are some issues that could not be resolved. (the top one shows the successrate of DAB+ frames passing a first test, the middle one the successrate of the Reed-Solomon error recovery on the frames passing the first test, and the bottom one tells the successrate of the AAC decoding).

Finally, if the service carries a picture as label, it will be displayed.

Reset button Touching the button labeled *reset* will, as the name suggests, instruct the software to do a reset on the selected channel, i.e. synchronization will be done again and a fresh list of services is built up.

Scan button Touching the button labeled *Scan* will instruct the software to perform a single scan over the channels in the currently selected band (default Band III) and show the results, see figure 6(i.e. the names of the ensembles found, names of services and some technical data on the services).

qt-dab					
	scan result	2	3	4	5
1		5B	MTVNL	8181	SNR 12
2	serviceName	serviceId	type	bit rate	protection level co
3	BBC ...	6335	DAB+	48	EEP 3-A 1/2
4	classicnl	83C3	DAB+	64	EEP 3-A 1/2
5	Omroep West	8419	DAB+	48	EEP 3-A 1/2

Figure 6: Fragment of the scan output

TII button Touching the button labeled *TII* will instruct the software to show a widget (figure 7) with the spectrum of the null period between DAB frames. The TII data is extracted from the spectrum of such null periods. On touching the button again the widget will disappear.

corr-result button Touching the button labeled *corr-result* will instruct the software to show a separate widget, making the *correlation result* for time synchronization visible. As mentioned earlier, DAB is transmitted in a Single Frequency Network and a receiver may receive data from more than one transmitter. The transmitter with the signal with the largest value for the correlation is the selected one.

The X-axis indicates the sample numbers. The picture, figure 8, shows that there are two peaks in the displayed region, on around sample 470 and one near 500. The

Figure 7: TII spectrum

latter is slightly stronger. Given that the samplerate is 2048000, one can conclude that the strongest signal arrives app 15 microseconds after the other one.

Touching the button again will cause the widget to disappear.

Figure 8: Correlation result

Spectrum button Touching the button labeled *Spectrum* will instruct the software to show a separate widget, displaying the spectrum of the incoming signal, showing the constellation of the received and decoded signal and will give a measure of the quality of the signal (higher is better). The picture, figure 9 shows a reasonable though not excellent signal. Ideally the constellation shows as four dots, one in each quadrant. The more the constellation looks like a collection of clouds, the poorer the signal.

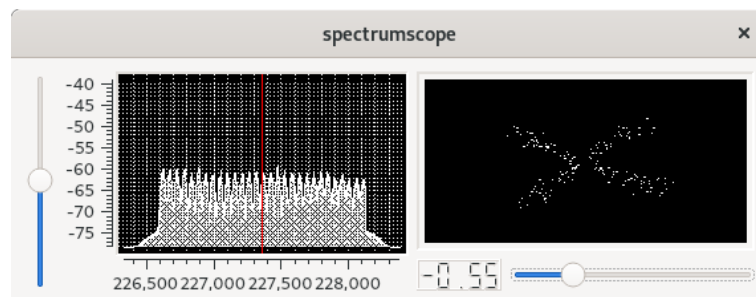

Figure 9: Spectrum of the signal

As with the other buttons, touching the button again will cause the widget to disappear.

hide button Touching the button labeled *hide* will hide (or show) the widget for the device control. The text on the button shows what the action following touching it is (i.e. *hide* or *show*).

The combobox labeled *default* The combobox, labeled *default* in the picture is for selecting an audio channel. What the combobox shows depends on the computer where the program is running. In most cases *default* will do.

The combobox, labeled *sdrplay* The combobox labeled *sdrplay* in the picture is for selecting a device. Depending on the configuration of the software device names will show here.

xx button The button labeled *xx* instructs the software to list the elements in the *history file*. Inspired by my car radio a list is maintained of all services ever selected. Touching the *xx* button again will hide the list.

Raw dump button Touching the button labeled *Raw dump* will instruct the software to dump the raw input samples into a file. First, a menu is presented for selecting a filename. Touching the button again will stop dumping and the file will be closed. The file is in PCM format, with a rate of 2048000, 2 channels and data represented as short ints. Note that recorded files will be pretty large, per second more than 8 MByte is written.

frame dump button Touching the button labeled *frame dump* will instruct the software to write the AAC output of the selected DAB+ service to a file. First, a menu is presented for selecting a filename. As usual, touching the button again will close the file. The resulting file can be used as input to e.g. VLC for further decoding.

audio dump button Touching the button labeled *audio dump* will instruct the software to write the audio output of the currently selected service, to written to a file. First a menu is presented for selecting a filename. The file, a PCM formatted file, is written with samplerate 48000, 2 channels and int16 format. Touching the button again will stop writing and close the file.

3 Command line parameters and the ini file

While the GUI provides control elements, some settings can be done via the command line and by setting values in the ".ini" file. This ".ini" file also contains settings recorded

by the software. Its default name and location is *.qt-dab.ini* which is kept in the users home directory.

On starting Qt-DAB via the command line (a few) parameters can be passed:

- "-i filename" to use the file named as ".ini" file rather than ".qt-dab.ini" which is stored in the users home directory;
- "-P portnumber" to use the portnumber as port for *TPEG* output in the Transparent Data Channel (tdc).
- "-A filename" to use the (name, integer) pairs in the file as channel definitions rather than the channels in Band III;
- "-T" generate messages while processing on success and misses in the various decoding steps.

Furthermore, a number of settings can be done in the ".ini" file (the default one or the user defined one, depending on the command line parameters). Note that the software itself also uses the ini file to store some settings.

- dabMode: While the *default* Mode for DAB is Mode 1, Qt-DAB provides the possibility to use Mode 2 or 4 by setting "dabMode=X" (X in {1, 2, 4});
- dabBand: While the *default* DAB band is Band III, Qt-DAB provides the possibility to use the L Band by setting "dabBand=L_Band". Note that setting a value here overrides the band setting by using command line parameters;
- displaycolor: While the *default* setting of the background color of the various displays is *black*, setting "displaycolor=xxx" will set the background of the displays to the selected color (e.g. "white");
- gridcolor: While the *default* setting of the color of the grids and the brushes in the various displays is *white*, setting "gridcolor=xxx" will set both the gridcolor as the color of the brush to the selected color (e.g. "red");
- displaySize: While the *default* setting of the size of the X axis of the spectrum and the TII display is 1024, setting "displaySize=xxx" will set the size of the X axis to xxx, provided xxx is a power of 2;
- plotLength: While the *default* setting of the size of the segment to be seen in the correlation viewer is 1000 (i.e. the correlation is shown over the first 1000 samples of the datablock), setting "plotLength=xxx" will show the correlation result over only xxx samples (centered around the maximum correlation value);
- saveSlides: While the *default* is 1, implying that decoded slides are saved, setting "saveSlides=0" will prevent slides to be saved;

- **pictures:** While the *default* path for storing slides and pictures is the directory "qt-pictures" in the /tmp directory, setting "pictures=xxx" will use the folder "xxx" for that purpose.
- **epgPath:** While the *default* value is the empty string, implying that files generated by the epg handler are not saved, setting "epgPath=XXX" will use the "XXX" (if not the empty string) as path to these files (assuming the path exists and the epg handler is configured in).
- **filePath:** While the *default* value is the empty string, implying that MOT files other than slides and epg files, are not saved, setting "filePath=XXX" will use "XXX" (if not the empty string) as path to these files (assuming the path exists).
- **serviceOrder:** While the *default* order to display the services in the list of services is alphabetically, setting "serviceOrder=1" will cause the services to be displayed based on the order of their serviceIds;
- **normalScan:** While the *default* way a scan is performed is as a single scan over all channels in the band, at the end displaying the result, setting "normalScan=1" will instruct the software to start scanning at the currently selected channel and stop scanning as soon as a channel is encountered with DAB data;
- **history:** While the *default* file for storing (and reading back) the history elements is ".qt-history.xml" in the users home directory, setting "history=xxx" will use the file here denoted as "xxx";
- **switchTime:** While the *default* maximum delay taken into account to select a preset value is 8000 milliseconds, setting "switchTime=xxx" will use "xxx" (if specified as number) instead;
- **latency:** While the *default* value for the latency, i.e. the delay in handling the audio, and determining the size of the audio buffers, is 5, setting "latency=xxx" will set the value to "xxx" (if specified as positive number);
- **ipAddress:** While the *default* ip address for sending datagrams to (obviously only meaningful if configured) is "127.0.0.1", setting "ipAddress=XXX" will use "XXX" as ip address (if properly specified);
- **port:** While the *default* port address for sending datagrams to (obviously only meaningful if configured) is "8888", setting "port=XXX" will use "XXX" (if specified as positive number);
- **threshold:** While the *default* value for the threshold is 3, another value can be set by "threshold=XXX". The threshold is a value used in the time synchronization. If the maximum correlation found is at least *threshold* times the average correlation value, the maximum is considered to be OK;

- `diff_length`: While the *default* value for the length of the segment used to find the correct coarse frequency offset is 40, another value can be chosen by setting "`diff_length=XXX`"; Note that the length does have impact on the amount of computations that are needed to compute an estimate of the frequency offset.
- `tii_delay`: While the *default* value for the number of DAB frames that will be skipped before recomputing the TII value is 5 (basically to reduce the computational load), another value can be chosen by setting "`tii_delay=XXX`";
- `tii_depth`: While the *default* value for the `tii_depth` (i.e. the number of spectra used to extract the TII values) is "1", another value can be chosen by setting "`tii_depth=XXX`";
- `echo_depth`: While the *default* value for the `echo_depth` is 1 (i.e. the maximum amount of alternative peaks in the correlation), another value can be chosen by setting "`echo_depth=XXX`";

4 Supported input devices

The current version of Qt-DAB supports a variety of input devices, the SDRplay, the AIRspy, the hackrf, the limeSDR and the RT2832 based sticks. Furthermore, there is support for devices for which a *Soapy* interface is defined, and there is support for file input.

4.1 The SDRplay RSP

The Qt-DAB software supports all RSP's from SDRplay. Qt-DAB provides support for devices using the 2.13 SDRplay interface library, and it supports devices using the 3.06 SDRplay interface library.

Figure 10: The two control widgets for the SDRplay

As figure 10 shows, the control widgets for the two different versions resemble each other. Both have spinboxes for setting the *if gain reduction*, the *lna state* and a *ppm offset*.

An optimal value for the *ppm offset* is to be determined experimentally, the RSP II, as used here, is happy with a ppm offset 0, the oscillator error is almost zero.

The spinbox for the *if gain reduction* is programmed to support the range of values between 20 and 59. The range of values for the *lna state* depends on the model of the RSP. The software will detect the model and fill in the range accordingly.

If the *agc* is selected, the *if gain reduction* spinbox will be hidden, its value is then irrelevant.

The RSP II has two (actually 3) slots for connecting an antenna. If an RSP II is detected, a combobox will be made visible for *antenna selection*.

A similar combobox exists for selecting a tuner in the widget for the 2.13 library controller. The SDRplay duo has two tuners. If the software detects the duo, a combobox will be made visible for selecting a tuner (Note that this feature is not tested).

Finally, both versions of the control widget contain a *dump* button. If touched the raw input from the connected device will be stored in a so-called xml formatted file. First a menu is shown for selecting a filename. As usual, touching the button again will stop dumping and the file will be closed.

4.2 The AIRSpy

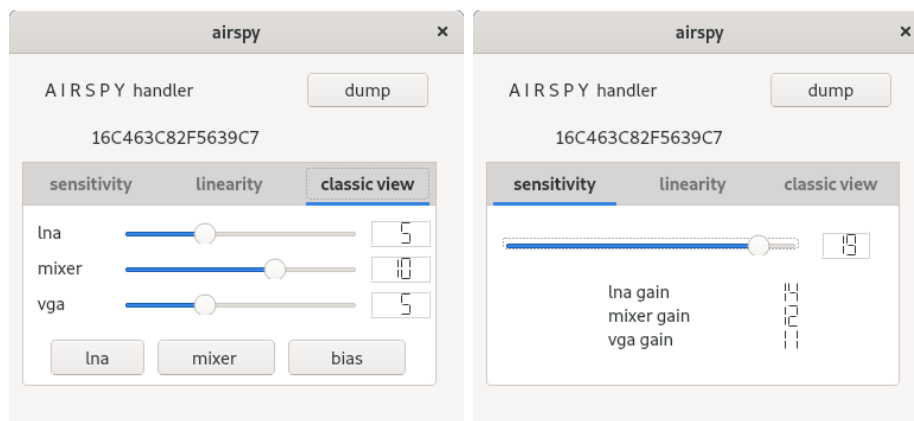

Figure 11: Widgets for AIRspy control

The control widget for the AIRspy (figure 11, left) contains three sliders and a push button. The sliders are to control the lna gain, the mixer gain and the vga gain.

To ease balancing the setting of the sliders, two combined settings are included in the widget, selectable by the tab *sensitivity* and *linearity*. Figure 11 right side, shows the setting at selecting the tab *sensitivity*.

Touching the button labeled *dump* instructs the software to dump the raw stream of samples into a file in the xml format (Note that while processing DAB requires the samplerate to be 2048000, that rate is not supported by the AIRspy, implying that the driver software has to do some rate conversion. The xml file though will just contain the samples on the rate before conversion).

4.3 The hackrf

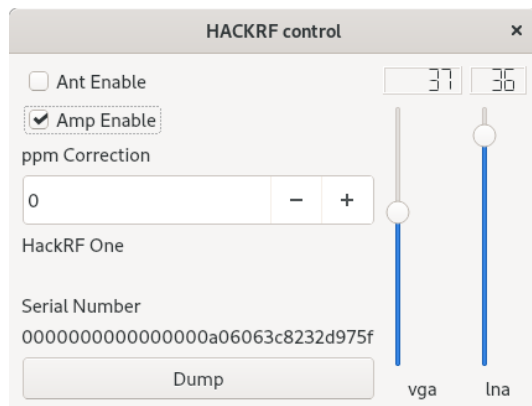

Figure 12: Widget for hackrf control

The control widget for hackrf (figure 12) shows, next to the Serial Number of the device, a few sliders, a few checkboxes, a spinbox and a push button.

- the *sliders* are there for controlling the lna and vga gain, the slider values are limited to the range of possible values;
- The *Ant Enable* checkbox is for Antenna port Power control (not used in this controller);
- The *Amp Enable* checkbox is - if enabled - for additional gain on the antenna input;
- the *ppm correction* spinbox can be set to correct the oscillator (on 227 MHz, the Qt-DAB software reports an offset of somewhat over 3 KHz);
- the Dump push button when pushed start dumping the raw input in xml file format. Touching the button again will halt the dumping and close the file.

4.4 The LimeSDR

On selecting the LimeSDR (if configured), a control widget for the LimeSDR appears (figure 13). The widget contains just three controls:

Figure 13: Widget for lime control

- *gain* control, with predefined values;
- *antenna select*, where *Auto* is usually the best choice;
- *dump*, if touched, the raw input from the connected device will be written to a file in the so-called xml format.

4.5 The RTLSDR stick

On selecting the dabstick (i.e. RT2832 based devices) (if configured), a control widget for the device appears (figure 14).

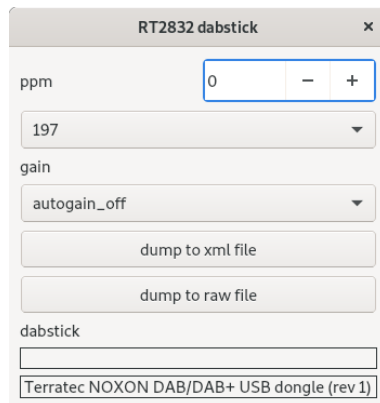

Figure 14: Widget for rtlshr device

The widget contains just a few controls:

- a spinbox for setting the ppm. Note that on average the offset of the oscillator with DABsticks is (much) larger than that with devices like the SDRplay;

- a combobox for setting the gain. The support software for RT2832 based devices generates a list of allowable gain settings, these settings are stored in the combobox;
- a combobox for setting the autogain;
- a push button that, when touched, will instruct the software to dump the raw input in the aforementioned xml format. At first a menu appears for selecting a file. Touching the button again will stop dumping and close the file.

4.6 Support for Soapy

Soapy is a generic device interface, a kind of wrapper to provide a common interface to a whole class of devices. Qt-DAB supports Soapy, and its use is tested with the Soapy interface for the SDRplay.

Figure 15: Widget for soapy

The widget for soapy control (see figure 15) when applied to the Soapy interface for the SDRplay contains the obvious controls, similar to that of the regular control for the SDRplay.

4.7 File input

Qt-DAB supports both writing raw input files and reading them back. Writing a file is initiated by either the *Raw dump* button on the main GUI, or by the *dump* button on the various device widgets. Qt-DAB differentiates between

- raw 8 bit files as generated by e.g. Osmocom software (usually files with an extension ".raw" or ".iq");

- PCM (i.e. ".wav") files, provided the data is 2 channels and with a samplerate of 2048000, generated by Qt-DAB and with an extension ".sdr";
- xml files. The xml file format was defined by Clemens Schmidt and me and aims at saving files in the original format. In order to support proper decoding of the contents, the data in the file is preceded by a detailed description in xml, hence the name xml file format.

When selecting file input ".raw" or ".wav", a simple widget is shown (figure 16), with as indication the number of seconds the file is being played.

Figure 16: Widgets for file input

Since processing an xml file implies some interpretation, the widget (figure 17) for control when reading an xml file is slightly more complex. It contains - next to the progress in reading the data - a description of the contents of the file. So, the program that generated the file as well as the device used in that program are displayed, the number of bits of the samples, as well as the number of elements is displayed as is the samplerate of recording and the frequency of the recording.

Figure 17: Widget for xml file input

5 Configuring and building an executable

5.1 Introduction

While for both Windows and Linux-x64 there are ready-made executables for installing resp. executing the Qt-DAB program, there are situations where one wants (or needs) to create its own version. For e.g. use of the software on an RPI one has to create an executable, for e.g. using the software with other or non-standard configured devices one has to create an executable. This section will describe the configuration options and the building process.

5.2 What is there to configure

The Qt-DAB software can be built using either qmake or cmake generating a Makefile. The current *configuration file* for qmake, *qt-dab.pro* has more options for configuring than *CMakeLists.txt*, the configuration file for use with cmake.

QMake and CMake take a different approach, while the configuration options for use with Qmake requires some editing in the *qt-dab.pro* file, selecting configuration options with cmake is ususally through command line parameters.

Note that the *qt-dab.pro* file contains a section *unix* and a section *win* for Windows. The *CMakeLists.txt* file is only used for Linux-x64.

5.2.1 Finding the right qwt library (qt-dab.pro only)

It turns out that linking the qwt library sometimes gives problems. While in fedora based systems, specifying linkage is as below, i.e. the *-lqwt-qt5* is the right one, in Debian based systems the line *-lqwr* line should be chosen by commenting out the other one.

```
#correct this for the correct path to the qwt6 library on your system
#LIBS          += -lqwt
LIBS           += -lqwt-qt5
```

5.2.2 Console or not (qt-dab.pro only)

```
# CONFIG += console
CONFIG -= console
```

While for tracing and debugging purposes it might be handy to see all the (text) output generated during execution, for normal use it is not. Including or excluding *console* in the configuration determines whether or not a console is present when executing.

5.2.3 Configurable common devices

Configuring devices is simple, for devices as mentioned above as well as for *rtl_tcp* the *qt-dab.pro* file contains a description. File input (all versions, i.e. raw files, sdr files and xml files) is standard configured in in Qt-DAB executables, modifying this implies changing the sources.

Using the qt-dab.pro file For configuring devices in the *qt-dab.pro* file, comment out or uncomment the line with the devicename.

```
CONFIG += dabstick
CONFIG += sdrplay-v2
CONFIG += sdrplay-v3
CONFIG += lime
CONFIG += airspy
CONFIG += hackrf
CONFIG += soapy
CONFIG += rtl_tcp
```

Note that for *lime* there is no support in generating a windows executable.

Using the CMakeLists.txt file The CMakeLists.txt file contains support for AIRspy, SDRplay, SDRplay_V3, RTLSDR, Hackrf and LimeSDR. Including a device in the configuration is by adding "-DXXX=ON" to the command line, where XXX stands for the device name.

5.2.4 Configuring SSE

In the deconvolution of the data in the FIC blocks, use is made of deconvolution code generated by the spiral code generator. If the code is to run on an x86-64 based PC, a speed up can be obtained by using the code generated for use with SSE instructions. Of course, the compiler has to support generating the right instructions, as far as known, the Mingw compiler, used for generating the windows executable does not.

The qt-dab.pro file contains in the unix section

```
#For x64 linux system uncomment SSE
#For any other system comment SSE out and uncomment NO_SSE
#CONFIG += SSE
CONFIG += NO_SSE
```

When using cmake, pass "-DVITERBI_SSE=ON" as command line parameter.

5.2.5 Configuring audio

- When running the Qt-DAB program remotely, e.g. on an RPI near a decent antenna, one might want to have the audio output sent through an IP port (a simple listener is available).
- Maybe one wants to use the audio handler from Qt.
- The default setting is for use of *portaudio* to send the PCM samples to a selected channel of the soundcard.

The *Linux* configuration for the Qt-DAB program offers in the qt-dab.pro file the possibility of configuring the audio output:

```
#if you want to listen remote, uncomment
#CONFIG += tcp-streamer          # use for remote listening
#otherwise, if you want to use the default qt way of sound out
#CONFIG += qt-audio
#comment both out if you just want to use the "normal" way
```

If cmake is used, pass "-DTCP_STREAMER=ON" as parameter for configuring the software for remote listening, use "-DQT_AUDIO=ON" for qt audio, or do not specify anything for using portaudio in the configuration.

Note that the configuration for Windows is only for "portaudio".

5.2.6 Configuring TPEG in the tdc

Handling TPEG in the tdc is only partially supported. Interpretation of the data is not part of the Qt-DAB software, however, the software is able to extract the TPEG frames and send these to an IP port.

In the qt-dab.pro file, we have

```
#very experimental, simple server for connecting to a tdc handler
CONFIG += datastreamer
```

In cmake the parameter "-DDATA_STREAMER=ON" can be passed to include handling TPEG as described in Qt-DAB.

5.2.7 Configuring IP datastream (qt-dab.pro only)

IP data can be extracted from the DAB stream and send out through an IP port.

```
#to handle output of embedded an IP data stream, uncomment
CONFIG += send_datagram
```

Note that - if not specified in the ini file - defaults are used for ip address and port.

5.2.8 Selecting an AAC decoder (qt-dab.pro only)

By default the *faad* library is used to decode AAC and generate the resulting PCM samples. An alternative is to use the *fdk-aac* library to decode AAC (contrary to the libfaad the fdk-aac library is able to handle newer versions of the AAC format, these newer versions are not used in DAB (DAB+)).

Selecting the library is by commenting out or uncommenting the appropriate line in the file *qt-dab.pro*.

```
CONFIG      += faad
#CONFIG      += fdk-aac
```

5.2.9 Configuring threading

Processing DAB (DAB+) requires quite some processing power. On small computers like an RPI2, performing all processing on a single CPU core overloads the core.

In order to allow smooth processing on multi core CPU's, an option is implemented to partition the workload. In order to partition processing, uncomment

```
DEFINES += __THREADED_BACKEND
```

in the *qt-dab.pro* file.

In case cmake is used, edit the file CMakeLists.txt and comment out or uncomment the line

```
#add_definitions (-D__THREADED_BACKEND) # uncomment for use for an RPI
```

5.2.10 Configuring EPG processing

By default MOT sections with EPG data are not dealt with. The Qt-DAB sourcetree contains software other sources that can be connected. If configured, decoded EPG data will be written into a file in xml format.

In order to configure the software to include the epg handling part uncomment

```
CONFIG      += try-epg
```

in the *qt-dab.pro* file, or add

```
-DTRY_EPG
```

to the command line when using cmake.

5.3 Preparing the build: loading libraries

5.3.1 Installing the libraries

As said, prior to compiling, some libraries have to be available. For Debian based systems (e.g. Ubuntu for PC and Stretch for the RPI) one can load all required libraries with the script given below.

```
sudo apt-get update
sudo apt-get install git cmake
sudo apt-get install qt5-qmake build-essential g++
sudo apt-get install pkg-config
sudo apt-get install libsndfile1-dev qt5-default
sudo apt-get install libfftw3-dev portaudio19-dev
sudo apt-get install libfaad-dev zlib1g-dev rtl-sdr
sudo apt-get install libusb-1.0-0-dev mesa-common-dev
sudo apt-get install libgl1-mesa-dev libqt5opengl5-dev
sudo apt-get install libsamplerate0-dev libqwt-qt5-dev
sudo apt-get install qtbase5-dev
```

5.3.2 Downloading of the sourcetree

Since the script also loads *git* the sourcetree for Qt-DAB (including the sources for dab-mini) can be installed by downloading by

```
git clone https://github.com/JvanKatwijk/qt-dab.git
```

5.3.3 Installing support for the RTLSDR stick

It is advised - when using an RTLSDR based "dab" stick - to create the library for supporting the device

```
git clone git://git.osmocom.org/rtl-sdr.git
cd rtl-sdr/
mkdir build
cd build
cmake ../ -DINSTALL_UDEV_RULES=ON -DDETACH_KERNEL_DRIVER=ON
make
sudo make install
sudo ldconfig
cd ..
rm -rf build
```

5.3.4 Installing support for the AIRspy

If one wants to use an AIRspy, a library can be created by

```
wget https://github.com/airspy/host/archive/master.zip
unzip master.zip
cd airspyone_host-master
mkdir build
cd build
cmake ../ -DINSTALL_UDEV_RULES=ON
make
sudo make install
sudo ldconfig
cd ..
rm -rf build
```

5.3.5 Installing support for SDRplay RSP

If one wants to use an RSP from SDRplay, one has to load and install the library from "www.SDRplay.com".

5.4 Finally: building an executable

5.4.1 Using cmake to build the executable

After installing the required libraries, and after editing the configuration, compiling the sources and generating an executable is simple.

Using cmake, creating an executable with as devices the SDRplay, the AIRspy, and the RTLSDR based dabsticks, the following script can be used:

```
cd qt-dab
mkdir build
cd build
cmake .. -DSDRPLAY=ON -DAIRSPY=ON -DRTLSDR=ON
make
```

The CMakeLists.txt file contains instructions to install the executable in "/usr/bin".

```
sudo make install
```

5.4.2 Using qmake to build the executable

Assuming the file qt-dab.pro is edited, the same result can be obtained by

```
cd qt-dab
qmake
make
```

In some Linux distributions replace qmake by qmake-qt5!

The *qt-dab.pro* file contains in both the section for unix as for windows a line telling where to put the executable

```
DESTDIR          = ./linux-bin
```

6 Adding support for a device

Qt-DAB is an open source project. Anyone is invited to suggest improvements, to improve the code and to add code for e.g. yet unsupported devices. While Qt-DAB can be configured for a variety of devices (basically the devices I have access to), there is obviously a multitude of other devices.

The Qt-DAB software provides a simple, well-defined interface between to ease interfacing a different device. The interface is defined as

```
class deviceHandler: public QObject {
public:
    deviceHandler (void);
    virtual ~deviceHandler (void);
    virtual int32_t getVFOFrequency (void);
    virtual int32_t defaultFrequency(void);
    virtual bool restartReader (int32_t);
    virtual void stopReader (void);
    virtual int32_t getSamples (std::complex<float> *, int32_t);
    virtual int32_t Samples (void);
    virtual void resetBuffer (void);
    virtual int16_t bitDepth (void) { return 10;}
    virtual void show ();
    virtual void hide ();
    virtual bool isHidden ();
};
```

A description of the interface elements follows

- *getVFOFrequency* returns the current oscillator frequency;
- *defaultFrequency* return a frequency in the range of valid frequencies;
- *restartReader* is supposed to start or restart the generation of samples from the device. Note that while not specified explicitly the assumed samplerate is 2048000, with a bandwidth of 1536000 Hz. The parameter indicates the frequency to be selected.
- *stopReader* will do the opposite of *restartReader*, collecting samples will stop;
- *getSamples* is the interface to the samples. The function should provide a given amount of samples, the return value is the number of samples actually read.
- *Samples* tells the amount of samples available for reading. If the Qt-DAB software needs samples, the function *Samples* is continuously called (with the delay between the calls) until the required amount is available, after which *getSamples* is called.
- *resetBuffer* will clear all buffers. The function is called on change of channel.

- *bitDepth* tells the number of bits of the samples. The value is used to scale the Y axis in the various scopes and to scale the input values when dumping the input.
- The GUI contains a button to hide (or show) the control widget for the device. The implementation of the control for the device will implement - provided the control has a widget - functions to *show* and to *hide* the widget, and *isHidden*, to tell the status (visible or not).

Having an implementation for controlling the new device, the Qt-DAB software has to know about the device, which requires a change to the configuration file (here we take qt-dab.pro) and the file radio.cpp, the implementer of the main GUI.

Modification to the qt-dab.pro file Driver software for a new device, here called *newDevice*), should be a class *newDevice*, derived from the class *deviceHandler*.

It is assumed that the header is in a file *new-device.h*, the implementation in a file *new-device.cpp*, both stored in a directory *new-device*.

The name of the device driver for new device *newDevice* will be added to the list of devices, i.e.

```
CONFIG += AIRSPY
...
CONFIG += newDevice
```

Next, somewhere in the qt-dab.pro file a section describing XXX should be added

```
newDevice {
    DEFINES          += HAVE_NEWDEVICE
    INCLUDEPATH      += ./devices/new-device
    HEADERS          += ./devices/new-device/new-device.h \
                        .. add further includes to development files
    SOURCES          += ./devices/new-device/new-device.cpp
    FORMS            += ./devices/new-device/newdevice-widget.ui
    LIBS             += .. add here libraries to be included
}
```

Modifications to radio.cpp The file "radio.cpp" needs to be modified in three places

- In the list of includes add

```
#ifdef HAVE_NEWDEVICE
#include new-device.h
#endif
```

- The selectable devices are added to the combobox containing the list of device names.

```

#ifdef HAVE_AIRSPY
deviceSelector -> addItem ("airspy");
#endif

....

#ifdef HAVE_NEWDEVICE
deviceSelector -> addItem ("newDevice");
#endif

```

- If selected, the class implementing the device handler should be instantiated,

```

#ifdef HAVE_AIRSPY
if (s == "airspy") {
    try {
        inputDevice = new airspyHandler ....
    }
}
#endif

#ifdef HAVE_NEWDEVICE__
if (s == "newDevice") {
    try {
        inputDevice = new newDevice (...parameters..);
        showButtons ();
    }
    catch (int e) {
        QMessageBox::warning (this, tr ("Warning"),
                               tr ("newDevice not found\n"));
        return nullptr;
    }
}
else
#endif

```

7 dabMini

7.1 Why a dabMini

I often run DAB decoder(s) on an RPI2 or 3. Since these RPIs are headless, control is from my laptop. Sometimes I find the GUI of Qt-DAB too large, especially when my only concern is listening to the audio. In that case I do not need any of the push buttons and the comboboxes on the main GUI widget. While using dabRadio for that purpose (or qml-dab) for some time, I realised that most of the corrections and changes as applied to the sources for Qt-DAB were not applied to the sources of these programs.

So, in order to tackle that problem, a version with a small GUI was designed and implemented using the Qt-DAB sources. To ensure maintaining the consistency, a sub-directory was made in the Qt-DAB sources containing the (few) files special for use with

this dabMini. Interesting is that - next to changes to device handlers to accomodate for the demise of the device control widgets - only 2 files needed to be changed.

7.2 The GUI

Figure 18: dabMini

As picture 18 shows, the GUI is minimal. The *device control* is at the top right. Depending on the selected device, one or two spinboxes are shown together with a checkbox for the agc.

To the right of the service list, a channel selector is available, with a < (previous) and a > (next) button for easy scanning though the channels, and a < (previous) and > (next) button for easy scanning though the services in the service list.

The bottom of the GUI contains two comboboxes, the one labeled *Presets* is - as the name suggests - for the presets, the other one for selecting an audio channel on the soundcard.

7.3 Building an executable

The dabMini shares the sources with Qt-DAB. Since the control of devices is now part of the GUI, device handlers were adapted.

7.3.1 Installing the libraries

Install the libraries as given in a previous section.

7.3.2 Building using cmake

Creating an executable is pretty straightforward:

```
cd dab-mini
mkdir build
cd build
cmake .. -DSDRPLAY=ON -DAIRSPY=ON ... -DRTLSDR=ON
make
sudo make install
```

will build and install a version with support for the specified devices.

7.4 Building using qmake

Using qmake, the commands to create an executable in ”./linux-bin” are

```
cd dab-mini
qmake
make
```

note that in some Linux distributions in the command one should relace qmake by qmake-qt5.
